

Criterion E: Evaluation

Meeting Criteria for Success:

The simulation is able to predict physical interaction between the objects quite well. This is done using the BRigid library, which works very well. Issues that can come up if objects are moved by the user to clip into each other. In addition, the simulation does not simulate friction. The user is able to add and remove objects as well, with no apparent issues. The object selection and modification system is less consistent than the other two functions. However, it is still somewhat consistent.

Improvement for Future:

The biggest improvement that could be made to the simulation is to fix the bugs with the object selection and modification system. Additional features could include adding much more customizability to the simulation. Currently the simulation is limited to rectangular prisms and spheres. In addition, there are more aspects of the objects in the simulation that the user could be given access to for modification, such as velocity and angular velocity. Lastly, a toggle for friction could be added.
